## $\begin{array}{c} {\rm COMP20008~2021S1~workshop\ -~week\ 7} \\ {\rm Correlation} \end{array}$

Consider the following hypothetical dataset providing measurements for *Average Steps* per day and *Average Resting Heart Rate*, across a sample of 12 people.

| Person ID | Average Steps per day | Average Resting Heart Rate |
|-----------|-----------------------|----------------------------|
| 1         | 1000                  | 100                        |
| 2         | 2500                  | 105                        |
| 3         | 3000                  | 80                         |
| 4         | 5000                  | 77                         |
| 5         | 6000                  | 74                         |
| 6         | 9000                  | 70                         |
| 7         | 11000                 | 65                         |
| 8         | 14000                 | 63                         |
| 9         | 18000                 | 62                         |
| 10        | 19000                 | 61                         |
| 11        | 19500                 | 60.5                       |
| 12        | 22000                 | 55                         |
|           |                       |                            |

Visually, the data looks like this:

## Steps per day vs Heart Rate

- 1. Compute the Pearson correlation between Average Steps per day and Average Resting Heart Rate. Show your working. How would you interpret this correlation value?
- 2. Based on the Pearson correlation value, can one conclude that doing more steps per day will cause one's average resting heart rate to decrease? How else might it be interpreted?
- 3. Discretise the data as follows: Apply 3 bin equal frequency discretisation to *Average Steps per day* and 4 bin equal frequency discretisation to *Average Resting Heart Rate*. Show the values of the discretised features.
- 4. Using the discretised features, compute the entropies:  $H(Average\ Steps\ per\ day)$ ,  $H(Average\ Resting\ Heart\ Rate)$ ,  $H(Average\ Steps\ per\ day)$  |  $Average\ Resting\ Heart\ Rate$ ),  $H(Average\ Resting\ Heart\ Rate)$ ,  $H(Average\ Steps\ per\ day)$ .
- 5. Using the above information, compute the mutual information between Average Steps per day and Average Resting Heart Rate.
